

Directed occupancy (Figure-1 analogue): from S_0=(2, 2), action a^*=right
(the policy's action toward G=(4, 10)), continuing under the goal-directed policy π_g (k=20, d=8, γ=0.98).
FB's row is visibly more diffuse across the room than Density's; by total variation, FB's distance to the true row is 2−4× Density's (occupancy.csv), though neither collapses all the way to ρ.

Successor row out of the doorway D at k=20, d=8, γ=0.98: crossing (left column)
vs a failed/blocked action (right column). Each column shares one color scale across
the three rows; colored squares mark true / FB / Density identity.

Normalized action gap at D vs stickiness k, room reward, γ=0.98
(1 = matches the true gap; 0 = the fit cannot tell crossing from failing).
